

Formal Methods in Software Engineering

Satisfiability Modulo Theories — Spring 2025

Konstantin Chukharev

§1 First-Order Theories

Motivation

Consider the signature $\Sigma = \langle \Sigma^S, \Sigma^F \rangle$ for a fragment of number theory:

- $\Sigma^S = \{\text{Nat}\}$, $\Sigma^F = \{0, 1, +, <\}$
- $\text{rank}(0) = \text{rank}(1) = \langle \text{Nat} \rangle$
- $\text{rank}(+) = \langle \text{Nat}, \text{Nat}, \text{Nat} \rangle$
- $\text{rank}(<) = \langle \text{Nat}, \text{Nat}, \text{Bool} \rangle$

1. Consider the Σ -sentence: $\forall x : \text{Nat}. \neg(x < x)$

- Is it *valid*, that is, true under *all* interpretations?
- No, e.g., if we interpret $<$ as *equals* or *divides*.

2. Consider the Σ -sentence: $\neg \exists x : \text{Nat}. (x < 0)$

- Is it *valid*?
- No, e.g., if we interpret Nat as the set of *all* integers.

3. Consider the Σ -sentence: $\forall x : \text{Nat}. \forall y : \text{Nat}. \forall z : \text{Nat}. (x < y) \wedge (y < z) \rightarrow (x < z)$

- Is it *valid*?
- No, e.g., if we interpret $<$ as the *successor* relation.

Motivation [2]

In practice, we often *do not care* about satisfiability or validity in *general*, but rather with respect to a *limited class* of interpretations.

A practical reason:

- When reasoning in a particular application domain, we typically have *specific* data types/structures in mind (e.g., integers, strings, lists, arrays, finite sets, ...).
- More generally, we are typically *not* interested in *arbitrary* interpretations, but rather in *specific* ones.

Theories formalize this domain-specific reasoning: we talk about satisfiability and validity *with respect to a theory* or “*modulo a theory*”.

A computational reason:

- The validity problem for FOL is *undecidable* in general.
- However, the validity problem for many *restricted* theories, is *decidable*.

First-Order Theories

Hereinafter, we assume that we have an infinite set of variables X .

Definition 1 (Theory): A first-order *theory* \mathcal{T} is a pair $\langle \Sigma, M \rangle$, where

- $\Sigma = \langle \Sigma^S, \Sigma^F \rangle$ is a first-order signature,
- M is a class of Σ -interpretations over X that is *closed under variable re-assignment*.

Definition 2: M is *closed under variable re-assignment* if every Σ -interpretation that differs from one in M in the way it interprets the variables in X is also in M .

A theory limits the interpretations of Σ -formulas to those from M .

Theory Examples

Example: Theory of Real Arithmetic $\mathcal{T}_{\text{RA}} = \langle \Sigma_{\text{RA}}, M_{\text{RA}} \rangle$:

- $\Sigma_{\text{RA}}^S = \{\text{Real}\}$
- $\Sigma_{\text{RA}}^F = \{+, -, *, \leq\} \cup \{q \mid q \text{ is a decimal numeral}\}$
- All $\mathcal{I} \in M_{\text{RA}}$ interpret **Real** as the set of *real numbers* \mathbb{R} , each q as the *decimal number* that it denotes, and the function symbols in the usual way.

Example: Theory of Ternary Strings $\mathcal{T}_{\text{TS}} = \langle \Sigma_{\text{TS}}, M_{\text{TS}} \rangle$:

- $\Sigma_{\text{TS}}^S = \{\text{String}\}$
- $\Sigma_{\text{TS}}^F = \{\cdot, <\} \cup \{a, b, c\}$
- All $\mathcal{I} \in M_{\text{TS}}$ interpret **String** as the set $\{a, b, c\}^*$ of all finite strings over the characters $\{“a”, “b”, “c”\}$, symbol \cdot as string concatenation (e.g., $a \cdot b = ab$), and $<$ as lexicographic order.

\mathcal{T} -interpretations

Definition 3 (Reduct): Let Σ and Ω be two signatures over variables X , where $\Omega \supseteq \Sigma$, that is, $\Omega^S \supseteq \Sigma^S$ and $\Omega^F \supseteq \Sigma^F$.

Let \mathcal{J} be an Ω -interpretation over X .

The *reduct* \mathcal{J}^Σ of \mathcal{J} to Σ is a Σ -interpretation obtained from \mathcal{J} by restricting it to the symbols in Σ .

Definition 4 (\mathcal{T} -interpretation): Given a theory $\mathcal{T} = \langle \Sigma, M \rangle$, a *\mathcal{T} -interpretation* is any Ω -interpretation \mathcal{J} for some signature $\Omega \supseteq \Sigma$ such that $\mathcal{J}^\Sigma \in M$.

Note: This definition allows us to consider the satisfiability in a theory $\mathcal{T} = \langle \Sigma, M \rangle$ of formulas that contain sorts or function symbols not in Σ . These symbols are usually called *uninterpreted* (in \mathcal{T}).

\mathcal{T} -interpretations [2]

Example: Consider again the theory of real arithmetic $\mathcal{T}_{\text{RA}} = \langle \Sigma_{\text{RA}}, M_{\text{RA}} \rangle$.

All $\mathcal{J} \in M_{\text{RA}}$ interpret `Real` as \mathbb{R} and function symbols as usual.

Which of the following interpretations are \mathcal{T}_{RA} -interpretations?

1. $\text{Real}^{\mathcal{J}_1} = \mathbb{Q}$, symbols in Σ_{RA}^F interpreted as usual. ✗
2. $\text{Real}^{\mathcal{J}_2} = \mathbb{R}$, symbols in Σ_{RA}^F interpreted as usual, and $\text{String}^{\mathcal{J}_2} = \{0.5, 1.3\}$. ✓
3. $\text{Real}^{\mathcal{J}_3} = \mathbb{R}$, symbols in Σ_{RA}^F interpreted as usual, and $\log^{\mathcal{J}_3}$ is the successor function. ✓

\mathcal{T} -satisfiability, \mathcal{T} -entailment, \mathcal{T} -validity

Definition 5 (\mathcal{T} -satisfiability): A Σ -formula α is *satisfiable in \mathcal{T}* , or *\mathcal{T} -satisfiable*, if it is satisfied by *some* \mathcal{T} -interpretation \mathcal{I} .

Definition 6 (\mathcal{T} -entailment): A set Γ of formulas *\mathcal{T} -entails* a formula α , if every \mathcal{T} -interpretation that satisfies all formulas in Γ also satisfies α .

Definition 7 (\mathcal{T} -validity): A formula α is *\mathcal{T} -valid*, if it is satisfied by *all* \mathcal{T} -interpretations.

Note: A formula α is *\mathcal{T} -valid* iff $\emptyset \models \alpha$.

Example: Which of the following Σ_{RA} -formulas is satisfiable or valid in \mathcal{T}_{RA} ?

1. $(x_0 + x_1 \leq 0.5) \wedge (x_0 - x_1 \leq 2)$
2. $\forall x_0. (x_0 + x_1 \leq 1.7) \rightarrow (x_1 \leq 1.7 - x_0)$
3. $\forall x_0. \forall x_1. (x_0 + x_1 \leq 1)$

satisfiable, falsifiable
satisfiable, valid
unsatisfiable, falsifiable

FOL vs Theory

For every signature Σ , entailment and validity in “pure” FOL can be seen as entailment and validity in the theory $\mathcal{T}_{\text{FOL}} = \langle \Sigma, M_{\text{FOL}} \rangle$ where M_{FOL} is the class of *all possible* Σ -interpretations.

- Pure first-order logic = reasoning over *all* possible interpretations.
- Reasoning modulo a theory = *restricting* interpretations with some domain constraints.
- Theories make automated reasoning *feasible* in many domains.

Axiomatization

Definition 8 (Axiomatic theory): A first-order *axiomatic theory* \mathcal{T} is defined by a signature Σ and a set \mathcal{A} of Σ -sentences, or *axioms*.

In particular, an Ω -formula α is *valid* in an axiomatic theory \mathcal{T} if it is entailed by the axioms of \mathcal{T} , that is, every Ω -interpretation \mathcal{I} that satisfies all axioms of \mathcal{T} also satisfies α .

Given an axiomatic theory \mathcal{T} defined by Σ and \mathcal{A} , we can define a theory $\mathcal{T}' = \langle \Sigma, M \rangle$ where M is the class of all Σ -interpretations that satisfy all axioms in \mathcal{A} .

It is not hard to show that a formula α is valid in \mathcal{T} *iff* it is valid in \mathcal{T}' .

Axiomatization [2]

Note: Not all theories are first-order axiomatizable.

Example: Consider the theory \mathcal{T}_{Nat} of the natural numbers, with signature Σ with $\Sigma^S = \{\text{Nat}\}$, $\Sigma^F = \{0, S, +, <\}$, and $M = \{\mathcal{I}\}$ where $\text{Nat}^{\mathcal{I}} = \mathbb{N}$ and Σ^F is interpreted as usual.

Any set of axioms for this theory is satisfied by *non-standard models*, e.g., interpretations \mathcal{I} where $\text{Nat}^{\mathcal{I}}$ includes other chains of elements besides the natural numbers, e.g., $\mathbb{N}^{\mathcal{I}} = \{0, 1, 2, \dots\} \cup \{\omega, \omega + 1, \dots\}$.

These models *falsify* formulas that are *valid* in \mathcal{T}_{Nat} , e.g., $\neg\exists x. (x < 0)$ or $\forall x. ((x \doteq 0) \vee \exists y. (x \doteq S(y)))$.

Completeness of Theories

Definition 9: A Σ -theory \mathcal{T} is *complete* if for every Σ -sentence α , either α or $\neg\alpha$ is valid in \mathcal{T} .

Note: In a complete Σ -theory, every Σ -sentence is either valid or unsatisfiable.

Example: Any theory $\mathcal{T} = \langle \Sigma, M \rangle$ where all interpretations in M only differ in how they interpret the variables (e.g., \mathcal{T}_{RA}) is *complete*.

Completeness of Theories [2]

Example: The axiomatic (mono-sorted) theory of *monoids* with $\Sigma^F = \{\cdot, \varepsilon\}$ and axioms

$$\forall x. \forall y. \forall z. (x \cdot y) \cdot z \doteq x \cdot (y \cdot z) \quad \forall x. (x \cdot \varepsilon \doteq x) \quad \forall x. (\varepsilon \cdot x \doteq x)$$

is *incomplete*.

For example, the sentence $\forall x. \forall y. (x \cdot y \doteq y \cdot x)$ is **true** in some monoids (e.g. the integers with addition) but **false** in others (e.g. the strings with concatenation).

Completeness of Theories [3]

Example: The axiomatic (mono-sorted) theory of *dense linear orders without endpoints* with $\Sigma^F = \{<\}$ and axioms

$$\forall x. \forall y. (x < y) \rightarrow \exists z. ((x < z) \wedge (z < y)) \quad (\text{dense})$$

$$\forall x. \forall y. ((x < y) \vee (y < x) \vee (x = y)) \quad (\text{linear})$$

$$\forall x. \neg(x < x) \quad \forall x. \forall y. \forall z. ((x < y) \wedge (y < z) \rightarrow (x < z)) \quad (\text{orders})$$

$$\forall x. \exists y. (y < x) \quad \forall x. \exists y. (x < y) \quad (\text{without endpoints})$$

is *complete*.

Decidability

Recall that a set A is *decidable* if there exists a *terminating* procedure that, given an input element a , returns (after *finite* time) either “yes” if $a \in A$ or “no” if $a \notin A$.

Definition 10: A theory $\mathcal{T} = \langle \Sigma, M \rangle$ is *decidable* if the set of all *\mathcal{T} -valid* Σ -formulas is decidable.

Definition 11: A *fragment* of \mathcal{T} is a *syntactically-restricted subset* of \mathcal{T} -valid Σ -formulas.

Example: The *quantifier-free* fragment of \mathcal{T} is the set of all \mathcal{T} -valid Σ -formulas without any quantifiers.

Example: The *linear* fragment of \mathcal{T}_{RA} is the set of all \mathcal{T} -valid Σ_{RA} -formulas without multiplication (*).

Axiomatizability

Definition 12: A theory $\mathcal{T} = \langle \Sigma, M \rangle$ is *recursively axiomatizable* if M is the class of all interpretations satisfying a *decidable set* of first-order axioms \mathcal{A} .

Theorem 1 (Lemma): Every recursively axiomatizable theory \mathcal{T} admits a procedure $E_{\mathcal{T}}$ that *enumerates* all \mathcal{T} -valid formulas.

Theorem 2: For every *complete* and *recursively axiomatizable* theory \mathcal{T} , \mathcal{T} -validity is decidable.

Proof: Given a formula α , use $E_{\mathcal{T}}$ to enumerate all valid formulas. Since \mathcal{T} is complete, either α or $\neg\alpha$ will eventually (after *finite* time) be produced by $E_{\mathcal{T}}$. □

§2 Introduction to SMT

Common Theories in SMT

SMT traditionally focuses on theories with *decidable* quantifier-free *fragments*.

Recall: a formula α is *\mathcal{T} -valid* iff $\neg\alpha$ is *\mathcal{T} -unsatisfiable*.

Checking the (un)satisfiability of quantifier-free formulas in main background theories efficiently has a large number of applications in:

- hardware and software verification
- model checking
- symbolic execution
- compiler validation
- type checking
- planning and scheduling
- software synthesis
- cyber-security
- verifiable machine learning
- analysis of biological systems

Further, we are going to study:

- A few of those theories and their decision procedures.
- Proof systems to reason modulo theories automatically.

From QF to Cubes

The satisfiability of quantifier-free formulas in a theory \mathcal{T} is decidable iff the satisfiability in \mathcal{T} of *conjunctions of literals (cubes)* is decidable.

We are going to study a general extension of DPLL to SMT that uses decision procedures for *conjunctions of literals*. Thus, we will mostly focus on *conjunctions of literals*.

Theory of Uninterpreted Functions

Given a signature Σ , the most general theory consists of the class of *all* Σ -interpretations.

In fact, this is a *family* of theories parameterized by the signature Σ .

It is known as the theory of *equality with uninterpreted functions* \mathcal{T}_{EUF} , or the *empty theory*, since it is axiomatized by the empty set of axioms.

Validity, and so satisfiability, in \mathcal{T}_{EUF} is only *semi-decidable* (this is just a validity in FOL).

However, the satisfiability of *conjunctions* \mathcal{T}_{EUF} -*literals* is *decidable*, in polynomial time, using the *congruence closure* algorithm.

Example: $(a \doteq b) \wedge (f(a) \doteq b) \wedge \neg(g(a) \doteq g(f(a)))$ Is this formula satisfiable in \mathcal{T}_{EUF} ?

Theory of Real Arithmetic

The theory of real arithmetic \mathcal{T}_{RA} is a theory of inequalities over the real numbers.

- $\Sigma^S = \{\text{Real}\}$
- $\Sigma^F = \{+, -, *, <\} \cup \{q \mid q \text{ is a decimal numeral}\}$
- M is the class of interpretations that interpret `Real` as the set of *real numbers* \mathbb{R} , and the function symbols in the usual way.

Satisfiability in the full \mathcal{T}_{RA} is *decidable* (in worst-case doubly-exponential time).

Restricted fragments of \mathcal{T}_{RA} can be decided more efficiently.

Example: Quantifier-free linear real arithmetic (QF_LRA) is the theory of *linear* inequalities over the reals, where $*$ can only be used in the form of *multiplication by constants (decimal numerals)*.

The satisfiability of conjunctions of literals in QF_LRA is *decidable* in *polynomial time*.

Theory of Integer Arithmetic

The theory of integer arithmetic \mathcal{T}_{IA} is a theory of inequalities over the integers.

- $\Sigma^S = \{\text{Int}\}$
- $\Sigma^F = \{+, -, *, <\} \cup \{n \mid n \text{ is an integer numeral}\}$
- M is the class of interpretations that interpret Int as the set of *integers* \mathbb{Z} , and the function symbols in the usual way.

Satisfiability in \mathcal{T}_{IA} is *not even semi-decidable*!

Satisfiability of quantifier-free Σ -formulas in \mathcal{T}_{IA} is *undecidable* as well.

Linear integer arithmetic (LIA, also known as *Presburger arithmetic*) is decidable, but not efficiently (in worst-case triply-exponential time).

Theory of Arrays with Extensionality

The theory of arrays \mathcal{T}_A is useful for modelling RAM or array data structures.

- $\Sigma^S = \{A, I, E\}$ (arrays, indices, elements)
- $\Sigma^F = \{\text{read}, \text{write}\}$, where $\text{rank}(\text{read}) = \langle A, I, E \rangle$ and $\text{rank}(\text{write}) = \langle A, I, E, A \rangle$

Let a be a variable of sort A , variable i of sort I , and variable v of sort E .

- $\text{read}(a, i)$ denotes the value stored in array a at index i .
- $\text{write}(a, i, v)$ denotes the array that stores value v at index i and is otherwise identical to a .

Example: $\text{read}(\text{write}(a, i, v), i) \doteq_E v$

- Is this formula *intuitively* valid/satisfiable/unsatisfiable in \mathcal{T}_A ?

Example: $\forall i. (\text{read}(a, i) \doteq_E \text{read}(a', i)) \rightarrow (a \doteq_A a')$

- Is this formula *intuitively* valid/satisfiable/unsatisfiable in \mathcal{T}_A ?

Theory of Arrays with Extensionality [2]

The theory of arrays $\mathcal{T}_A = \langle \Sigma, M \rangle$ is finitely axiomatizable.

M is the class of interpretations that satisfy the following axioms:

1. $\forall a. \forall i. \forall v. (\text{read}(\text{write}(a, i, v), i) \doteq_E v)$
2. $\forall a. \forall i. \forall j. \forall v. \neg(i \doteq_I j) \rightarrow (\text{read}(\text{write}(a, i, v), j) \doteq_E \text{read}(a, j))$
3. $\forall a. \forall b. (\forall i. (\text{read}(a, i) \doteq_E \text{read}(b, i))) \rightarrow (a \doteq_A b)$

Note: The last axiom is called *extensionality* axiom. It states that two arrays are equal if they have the same values at all indices. It can be omitted to obtain a theory of arrays *without extensionality*.

Satisfiability in \mathcal{T}_A is *undecidable*.

There are several *decidable fragments* of \mathcal{T}_A .

Decidability and Complexity [2]

- “**Full**” denotes the decidability of a complete theory *with* quantifiers.
- “**QF**” denotes the decidability of a *quantifier-free* theory.
- “**Full complexity**” denotes the complexity of the satisfiability in a complete theory *with* quantifiers.
- “**QFC complexity**” denotes the complexity of the satisfiability in a quantifier-free *conjunctive* fragment of a theory.
- “*Not elementary recursive*” means the runtime cannot be bounded by a fixed-height stack of exponentials.

§4 Theory Solvers

Theory Solvers

Definition 13 (\mathcal{T} -solver): A *theory solver*, or \mathcal{T} -*solver*, is a specialized decision procedure for the satisfiability of conjunctions of literals in a theory \mathcal{T} .

Difference Logic

Definition 14: *Difference logic* is a fragment of linear integer arithmetic consisting of conjunctions of literals of the very restricted form:

$$x - y \bowtie c$$

where x and y are integer variables, c is a numeral, and $\bowtie \in \{=, <, \leq, >, \geq\}$.

A solver for difference logic consists of three steps:

1. Literals normalization.
2. Conversion to a graph.
3. Cycle detection.

Difference Logic [2]

Step 1: Rewrite each literal using \leq by applying the following rules:

1. $(x - y = c) \longrightarrow (x - y \leq c) \wedge (x - y \geq c)$
2. $(x - y \geq c) \longrightarrow (y - x \leq -c)$
3. $(x - y > c) \longrightarrow (y - x < -c)$
4. $(x - y < c) \longrightarrow (x - y \leq c - 1)$

Step 2: Construct a weighted directed graph G with a vertex for each variable and an edge $x \xrightarrow{c} y$ for each literal $(x - y \leq c)$.

Step 3: Check for *negative cycles* in G .

- Use, for example, the Bellman-Ford algorithm.
- If G contains a negative cycle, the set of literals is *inconsistent* (UNSAT).
- Otherwise, the set of literals is *consistent* (SAT).

Difference Logic Example

Consider the following set of difference logic literals:

$$(x - y = 5) \wedge (z - y \geq 2) \wedge (z - x > 2) \wedge (w - x = 2) \wedge (z - w < 0)$$

Normalize the literals:

- $(x - y = 5) \longrightarrow (x - y \leq 5) \wedge (y - x \leq -5)$
- $(z - y \geq 2) \longrightarrow (y - z \leq -2)$
- $(z - x > 2) \longrightarrow (x - z \leq -3)$
- $(w - x = 2) \longrightarrow (w - x \leq 2) \wedge (x - w \leq -2)$
- $(z - w < 0) \longrightarrow (z - w \leq -1)$

UNSAT because of the negative cycle: $x \xrightarrow{-3} z \xrightarrow{-1} w \xrightarrow{2} x$.

Satisfiability Proof Systems

Definition 15: A literal is *flat* if it is of the form:

- $x \doteq y$
- $\neg(x \doteq y)$
- $x \doteq f(z)$

where x and y are variables, f is a function symbol, and z is a tuple of 0 or more variables.

Note: Any set of literals can be converted to an equisatisfiable set of *flat* literals by introducing *new* variables and equating non-equational atoms to *true*.

Example: Consider the set of literals: $\{x + y > 0, y \doteq f(g(z))\}$.

We can convert it to an equisatisfiable set of flat literals by introducing fresh variables v_1, v_2 and v_3 :

$$\{ v_1 \doteq v_2 > v_3, \quad v_1 \doteq \text{true}, \quad v_2 \doteq x + y, \quad v_3 \doteq 0, \quad y \doteq f(v_4), \quad v_4 \doteq g(z) \}$$

Hereinafter, we will assume that all literals are *flat*.

Notation and Assumptions

- We abbreviate $\neg(s \doteq t)$ with $s \not\doteq t$.
- For tuples $\mathbf{u} = \langle u_1, \dots, u_n \rangle$ and $\mathbf{v} = \langle v_1, \dots, v_n \rangle$, we abbreviate $(u_1 \doteq v_1) \wedge \dots \wedge (u_n \doteq v_n)$ with $\mathbf{u} = \mathbf{v}$.
- Γ is used to refer to the “current” proof state in rule premises.
- $\Gamma, s \doteq t$ is an abbreviation for $\Gamma \cup \{s \doteq t\}$.
- If applying a rule R does not change Γ , then R *is not applicable* to Γ , that is, Γ is *irreducible* w.r.t. R .

A Satisfiability Proof System for QF_UF

Let QF_UF be the quantifier-free fragment of FOL over some signature Σ .

Below is a simple satisfiability proof system R_{UF} for QF_UF:

$$\mathbf{CONTR} \frac{x \doteq y \in \Gamma \quad x \not\doteq y \in \Gamma}{\text{UNSAT}}$$

$$\mathbf{REFL} \frac{x \text{ occurs in } \Gamma}{\Gamma := \Gamma, x \doteq x}$$

$$\mathbf{SYMM} \frac{x \not\doteq y \in \Gamma}{\Gamma := \Gamma, y \doteq x}$$

$$\mathbf{TRANS} \frac{x \not\doteq y \in \Gamma \quad y \doteq z \in \Gamma}{\Gamma := \Gamma, x \doteq z}$$

$$\mathbf{CONG} \frac{x \doteq f(u) \in \Gamma \quad y \doteq f(v) \in \Gamma \quad u = v \in \Gamma}{\Gamma := \Gamma, x \doteq y}$$

$$\mathbf{SAT} \frac{\text{No other rules apply}}{\text{SAT}}$$

Is R_{UF} *sound*?

Is R_{UF} *terminating*?

Example Derivation in R_{UF}

REFL $\frac{x \text{ occurs in } \Gamma}{\Gamma := \Gamma, x \doteq x}$	CONTR $\frac{x \doteq y \in \Gamma \quad x \not\doteq y \in \Gamma}{\text{UNSAT}}$	TRANS $\frac{x \not\doteq y \in \Gamma \quad y \doteq z \in \Gamma}{\Gamma := \Gamma, x \doteq z}$
SYMM $\frac{x \not\doteq y \in \Gamma}{\Gamma := \Gamma, y \doteq x}$	CONG $\frac{x \doteq f(u) \in \Gamma \quad y \doteq f(v) \in \Gamma \quad u = v \in \Gamma}{\Gamma := \Gamma, x \doteq y}$	SAT $\frac{\text{No other rules apply}}{\text{SAT}}$

Example: Determine the satisfiability of the following set of literals: $a \doteq f(f(a))$, $a \doteq f(f(f(a)))$, $g(a, f(a)) \not\doteq g(f(a), a)$. Flatten the literals and construct the following proof:

$$\begin{array}{l}
 \frac{a \doteq f(a_1), a_1 \doteq f(a), a \doteq f(a_2), a_2 \doteq f(a_1), a_3 \not\doteq a_4, a_3 \doteq g(a, a_1), a_4 \doteq g(a_1, a)}{\text{REFL}} \\
 \frac{a_1 \doteq a_1}{\text{CONG applied to } a \doteq f(a_1), a_2 \doteq f(a_1), a_1 \doteq a_1} \\
 \frac{a \doteq a_2}{\text{CONG applied to } a_1 \doteq f(a), a \doteq f(a_2), a \doteq a_2} \\
 \frac{a_1 \doteq a}{\text{SYMM}} \\
 \frac{a \doteq a_1}{\text{CONG applied to } a_3 \doteq g(a, a_1), a_4 \doteq g(a_1, a), a \doteq a_1, a_1 \doteq a} \\
 \frac{a_3 \doteq a_4}{\text{CONTR applied to } a_3 \doteq a_4, a_3 \not\doteq a_4} \\
 \text{UNSAT}
 \end{array}$$

Soundness

Theorem 3 (Refutation soundness): A literal set Γ_0 is unsatisfiable if R_{UF} derives UNSAT from it.

Proof: All rules except SAT are satisfiability-preserving.

If a derivation from Γ_0 ends with UNSAT, then Γ_0 must be unsatisfiable. □

Theorem 4 (Solution soundness): A literal set Γ_0 is satisfiable if R_{UF} derives SAT from it.

Proof: Let Γ be a proof state to which SAT applies. From Γ , we can construct an interpretation \mathcal{J} that satisfies Γ_0 . Let $s \sim t$ iff $(s \doteq t) \in \Gamma$. One can show that \sim is an equivalence relation.

Let the domain of \mathcal{J} be the equivalence classes E_1, \dots, E_k of \sim .

- For every variable or a constant t , let $t^{\mathcal{J}} = E_i$ if $t \in E_i$ for some i . Otherwise, let $t^{\mathcal{J}} = E_1$.
- For every unary function symbol f , and equivalence class E_i , let $f^{\mathcal{J}}$ be such that $f^{\mathcal{J}}(E_i) = E_j$ if $f(t) \in E_j$ for some $t \in E_i$. Otherwise, let $f^{\mathcal{J}}(E_i) = E_1$. Define $f^{\mathcal{J}}$ for non-unary f similarly.

We can show that $\mathcal{J} \models \Gamma$. This means that \mathcal{J} models Γ_0 as well since $\Gamma_0 \subseteq \Gamma$. □

Termination

Theorem 5: Every derivation strategy for R_{UF} terminates.

Proof: R_{UF} adds to the current state Γ only equalities between variables of Γ_0 .

So, at some point it will run out of new equalities to add.

□

Completeness

Theorem 6 (Refutation completeness): Every derivation strategy applied to an unsatisfiable state Γ_0 ends with UNSAT.

Proof: Let Γ_0 be an unsatisfiable state. Suppose there was a derivation from Γ_0 that did not end with UNSAT. Then, by the termination theorem, it would have to end with SAT. But then R_{UF} would be not be solution sound. □

Theorem 7 (Solution completeness): Every derivation strategy applied to a satisfiable state Γ_0 ends with SAT.

Proof: Let Γ_0 be a satisfiable state. Suppose there was a derivation from Γ_0 that did not end with SAT. Then, by the termination theorem, it would have to end with UNSAT. But then R_{UF} would be not be refutation sound. □
